# Water for Weapons Destruction: Source, Quantity, Groundwater Protection

The Pueblo Chemical Agent-Destruction Pilot Plant (PCAPP) will safely and efficiently destroy 2,611 tons of chemical agent stored at the U.S. Army Pueblo Chemical Depot (PCD). Technology known as neutralization followed by biotreatment will be used to destroy the mustard agent contained within projectiles and mortar rounds.

## Where does the PCD get water? How much is available for use at PCAPP?

A series of wells located on PCD property gives the depot an annual capacity of 177 million gallons of water. The depot pumps approximately 97 million gallons of that capacity each year, leaving a balance of 80 million gallons. Although these wells are located on the depot, all pumped water is purchased from the Pueblo Board of Water Works and the Colorado Water Protection Development Association.

Of this amount, about 50 million gallons per year is available for use by PCAPP and is nearly twice the amount needed to meet the plant's needs. The rest is available for other depot activities.

## How much water will the PCAPP facility use when the plant is operating?

PCAPP will use water for several purposes, such as neutralizing the mustard agent and cooling the processing equipment. During the operating life of the plant, total water usage is estimated to be about 58,000 gallons of water per day, or, 54 million gallons of water during its operating life. Water that is part of the process will be treated and reused, making the plant a zero discharge facility.

## How will groundwater be protected?

The plant is designed and will be operated to protect groundwater. The [Colorado Department of Public Health and Environment](#) (CDPHE) reviews and approves the design and operating procedures that protect groundwater. Measures to prevent groundwater contamination have been built into the facility and how CDPHE, will monitor plant operations to ensure permit requirements are met.

## What is currently known about groundwater and soil conditions at the PCAPP site?

Soil and groundwater samples have been taken from more than 80 locations at the PCAPP site. Data from this sampling will be compared to samples taken after the plant closes to verify that there is no contamination from plant operations.

Soil and water samples were taken from 43 locations within the plant footprint in 2004, and five groundwater monitoring wells were installed up gradient and down gradient from the plant site. Analysis of those samples did not find any metals or organic compounds above naturally occurring levels.

Samples were taken from an additional 41 locations in 2006 after the footprint of the plant changed during redesign. Analysis of these samples confirms the previous finding of no metals or organic compounds above naturally occurring levels.

PCAPP has been developed on a "Greenfield" site, which means there are no records or other data to indicate that the area has been used for hazardous materials management, or was subject to spills or chemical releases.
